Ageeva N.A. Psychophysical peculiarities of oncological patients in the context of bioethic problems of contemporary world

In the modern world it is topical to study topical problems of the individual cancer patient, and his position in the system of relations with the world, with other people and each other; to study issues relating to the specific role of the mind in the development of cancer disease. Most people with cancer (regardless of the variety of cancer) share common psychological characteristics that are manifested in the difficulties of emotional perception and response to stressful situations in a mythological and rational way of thinking, and a tendency to occupy the position of the infantile, some features of which were manifested before the rise of disease. The main characteristics of the socio-psychological portrait of a cancer patient are evidence of the need to respect the principle of differentiation of communicative approaches to the treatment of certain groups of patients, designed to meet the mental and physical characteristics of a particular individual, and bioethical issues of our time.

Key words: border situation, therapeutic alliance, infantilism, psychological correction.
