Technological problems of regulation of public health as a factor of national security of Russian society: social and philosophical aspect

It has been analyzed the main aspects of the technological problem of ensuring public health in the context of the national security of Russian society. It is shown that the technological problem of ensuring public health has two main aspects: 1) providing the Russian population with both affordable and highly technological medical diagnostic and therapeutic equipment; 2) the need to protect the population from industrial factors of environmental pollution by improving the technological level of production. Both aspects unite the need to create and maintain economic, legal and organizational links between industry and fundamental science. The importance of using environmentally friendly technologies in domestic industrial production is shown. If we accept public health as a medical and biological integral characteristic of the vital activity of a particular society, then environmental problems play the role of a primary and large-scale factor in ensuring Russia's national security.

Key words: technologies, public health, national security, Russian society.
